About This Manual

This guide contains details about using the derived APIs for Ruby, Perl, and Python to create scripts that interact correctly with the Perforce server.

These derived APIs depend on the C/C++ API. See the *Perforce C/C++ API User's Guide* for details.

Please give us feedback

If you have any feedback for us, or detect any errors in this guide, please email details to manual@perforce.com.

Introduction

P4Ruby is an extension to the Ruby programming language that allows you to run Perforce commands from within Ruby scripts, and get the results in a Ruby-friendly format.

The main features are:

- Get Perforce data and forms in hashes and arrays
- Edit Perforce forms by modifying hashes
- Exception based error handling
- Controllable handling of warnings such as "File(s) up-to-date." on a sync
- Run as many commands on a connection as required
- The output of a command is returned as a Ruby array. For non-tagged output, the elements of the array are strings. For tagged output, the elements of the array are Ruby hashes. For forms, the output is an array of `P4::Spec` objects.
- Thread-safe and thread-friendly; you can have multiple instances of the `P4` class running in different threads.
- Exception-based error handling. Trap `P4Exceptions` for complete, high-level error handling.

System Requirements

P4Ruby is supported on Windows, Linux, Solaris, and FreeBSD.

To build P4Ruby, your development machine must also have:

- Ruby 1.8 development files
- `make` (or `nmake` on Windows)
- The 2007.3 Perforce C/C++ API for your target platform
- The same C++ compiler used to build the Perforce C++ API on your target platform.

(If you get “unresolved symbol” errors when building or running P4Ruby, you probably used the wrong compiler or the wrong Perforce API build.)

Installing P4Ruby

Download P4Ruby from the Perforce web site downloads page. After downloading, you can either run the installer or build the interface from source, as described in the release notes.

Programming with P4Ruby

The following example shows how to create a new client workspace based on an existing template:

```
require "P4"
template = "my-client-template"
client_root = 'c:\p4-work'

p4 = P4.new
p4.connect
begin
    # Run a "p4 client -t template -o" and convert it into a Ruby hash
    spec = p4.fetch_client( "-t", template )

    # Now edit the fields in the form
    spec[ "Root" ] = client_root
    spec[ "Options" ] = spec[ "Options" ].sub( "normdir", "rmdir" )

    # Now save the updated spec
    p4.save_client( spec )

    # And sync it.
    p4.run_sync
rescue P4Exception
    # If any errors occur, we'll jump in here. Just log them
    # and raise the exception up to the higher level

    p4.errors.each { |e| $stderr.puts( e ) }
    raise
end
```

P4Ruby classes

The P4 module consists of several public classes:

- P4
- P4Exception
- P4::DepotFile
- P4::Revision
- P4::Integration
- P4::MergeData
- P4::Spec

The following tables provide brief details about each public class.

P4

The main class used for executing Perforce commands. Almost everything you do with P4Ruby will involve this class.

Method	Description
<code>identify</code>	Return the version of P4 in use (class method)
<code>new</code>	Construct a new P4 object (class method)
<code>api_level=</code>	Set desired API compatibility level
<code>api_level</code>	Return current API compatibility level
<code>at_exception_level</code>	Execute the associated block under a specific exception level, returning to previous exception level when block returns
<code>charset=</code>	Set character set when connecting to Unicode servers
<code>charset</code>	Get character set when connecting to Unicode servers
<code>client=</code>	Set client workspace (P4CLIENT)
<code>client</code>	Get current client workspace (P4CLIENT)
<code>connect</code>	Connect to the Perforce Server, raise P4Exception on failure
<code>connected?</code>	Test whether or not session has been connected and/or has been dropped
<code>cwd=</code>	Set current working directory
<code>cwd</code>	Get current working directory

Method	Description
<code>delete_spectype</code>	Shortcut methods for deleting clients, labels, etc.
<code>disconnect</code>	Disconnect from the Perforce Server
<code>errors</code>	Return the array of errors that occurred during execution of previous command
<code>exception_level=</code>	Control which types of events give rise to exceptions (P4::RAISE_NONE, RAISE_ERRORS, or RAISE_ALL)
<code>exception_level</code>	Return the current exception level
<code>fetch_spectype</code>	Shortcut methods for retrieving the definitions of clients, labels, etc.
<code>format_spec</code>	Convert fields in a hash containing the elements of a Perforce form (spec) into the string representation familiar to users
<code>format_spectype</code>	Shortcut methods; equivalent to: <code>p4.format_spec(spectype, aHash)</code>
<code>host=</code>	Set the name of the current host (P4HOST)
<code>host</code>	Get the current hostname
<code>input=</code>	Store input for next command
<code>maxlocktime=</code>	Set MaxLockTime used for all following commands
<code>maxlocktime</code>	Get MaxLockTime used for all following commands
<code>maxresults=</code>	Set MaxResults used for all following commands
<code>maxresults</code>	Get MaxResults used for all following commands
<code>maxscanrows=</code>	Set MaxScanRows used for all following commands
<code>maxscanrows</code>	Get MaxScanRows used for all following commands
<code>p4config_file</code>	Get the location of the configuration file used (P4CONFIG).
<code>parse_spectype</code>	Shortcut method; equivalent to: <code>p4.parse_spec(spectype, aString)</code>
<code>parse_spec</code>	Parses a Perforce form (spec) in text form into a Ruby hash using the spec definition obtained from the server.
<code>password=</code>	Set Perforce password (P4PASSWD)
<code>password</code>	Get the current password or ticket.
<code>port=</code>	Set host and port (P4PORT)
<code>port</code>	Get host and port (P4PORT) of the current Perforce server
<code>prog=</code>	Set the program name as shown by <code>p4 monitor show -e</code>

Method	Description
<code>prog</code>	Get the program name as shown by <code>p4 monitor show -e</code>
<code>run_cmd</code>	Shortcut method; equivalent to: <code>p4.run (cmd, arguments...)</code>
<code>run</code>	Runs the specified Perforce command with the arguments supplied.
<code>run_filelog</code>	Runs a <code>p4 filelog</code> on the <code>fileSpec</code> provided, returns an array of <code>P4::DepotFile</code> objects
<code>run_login</code>	Runs <code>p4 login</code> using a password (or other arguments) set by the user
<code>run_password</code>	A thin wrapper to make it easy to change your password.
<code>run_resolve</code>	Interface to <code>p4 resolve</code> .
<code>run_submit</code>	Submit a changelist to the server.
<code>save_spectype</code>	Shortcut methods; equivalent to: <code>p4.input = hashOrString</code> <code>p4.run(spectype, "-i")</code>
<code>server_level</code>	Returns the current Perforce server level.
<code>tagged=</code>	Toggles tagged output (true or false). By default, tagged output is on.
<code>tagged?</code>	Detects whether or not tagged output is enabled.
<code>ticketfile=</code>	Set the location of the <code>P4TICKETS</code> file
<code>ticketfile</code>	Get the location of the <code>P4TICKETS</code> file
<code>user=</code>	Set the Perforce username (<code>P4USER</code>)
<code>user</code>	Get the Perforce username (<code>P4USER</code>)
<code>version=</code>	Set the version of your script, as reported to the Perforce Server.
<code>version</code>	Get the version of your script, as reported to the Perforce Server.
<code>warnings</code>	Returns the array of warnings which arose during execution of the last command

P4Exception

Used as part of error reporting and is derived from the Ruby `RuntimeError` class.

P4::DepotFile

Utility class allowing access to the attributes of a file in the depot. Returned by `P4#run_filelog`.

Method	Description
<code>depot_file</code>	Name of the depot file to which this object refers
<code>each_revision</code>	Iterates over each revision of the depot file
<code>revisions</code>	Returns an array of revision objects for the depot file

P4::Revision

Utility class allowing access to the attributes of a revision `DepotFile` object. Returned by `P4#run_filelog`.

Method	Description
<code>action</code>	Action that created the revision
<code>change</code>	Changelist number
<code>client</code>	Client workspace used to create this revision
<code>depot_file</code>	Name of the file in the depot
<code>desc</code>	Short changelist description
<code>digest</code>	MD5 digest of this revision
<code>filesize</code>	Returns the size of this revision.
<code>integrations</code>	Array of <code>P4::Integration</code> objects
<code>revno</code>	Revision number
<code>time</code>	Timestamp
<code>type</code>	Perforce file type
<code>user</code>	User that created this revision

P4::Integration

Utility class allowing access to the attributes of an integration record for a `Revision` object. Returned by `P4#run_filelog`.

Method	Description
<code>how</code>	Integration method (merge/branch/copy/ignored)
<code>file</code>	Integrated file

Method	Description
<code>srev</code>	End revision
<code>erev</code>	Start revision

P4::MergeData

Class encapsulating the context of an individual merge during execution of a `p4 resolve` command. Passed as a parameter to the block passed to `P4#run_resolve`.

Method	Description
<code>your_name</code>	Returns the name of “your” file in the merge. (file in workspace)
<code>their_name</code>	Returns the name of “their” file in the merge. (file in the depot)
<code>base_name</code>	Returns the name of “base” file in the merge. (file in the depot)
<code>your_path</code>	Returns the path of “your” file in the merge. (file in workspace)
<code>their_path</code>	Returns the path of “their” file in the merge. (temporary file on workstation into which <code>their_name</code> has been loaded)
<code>base_path</code>	Returns the path of the base file in the merge. (temporary file on workstation into which <code>base_name</code> has been loaded)
<code>result_path</code>	Returns the path to the merge result. (temporary file on workstation into which the automatic merge performed by the server has been loaded)
<code>merge_hint</code>	Returns hint from server as to how user might best resolve merge
<code>run_merge</code>	If the environment variable <code>P4MERGE</code> is defined, run it and return a boolean based on the return value of that program

P4::Spec

Subclass of hash allowing access to the fields in a Perforce specification form. Also checks that the fields that are set are valid fields for the given type of spec. Returned by `P4#fetch_spectype`.

Method	Description
<code>spec._fieldname</code>	Return the value associated with the field named <i>fieldname</i> .
<code>spec._fieldname=</code>	Set the value associated with the field named <i>fieldname</i> .
<code>spec.permitted_fields</code>	Returns an array containing the names of fields that are valid in this spec object.

Class P4

Description

Main interface to the Perforce client API. Each `P4` object provides you with a thread-safe API level interface to Perforce. The basic model is to:

1. Instantiate your `P4` object
2. Specify your Perforce client environment
 - `client`
 - `host`
 - `password`
 - `port`
 - `user`
3. Set any options to control output or error handling:
 - `exception_level`
4. Connect to the Perforce Server
5. Run your Perforce commands
6. Disconnect from the Perforce Server

Class Methods

P4.identify -> aString

Return the version of P4 that you are using.

```
ruby -rP4 -e 'puts( P4.identify )'
```

P4.new -> aP4

Constructs a new `P4` object.

```
p4 = P4.new()
```

Instance Methods

p4.api_level= anInteger -> anInteger

Sets the API compatibility level desired. This is useful when writing scripts using Perforce commands that do not yet support tagged output. In these cases, upgrading to a later server that supports tagged output for the commands in question can break your script. Using this method allows you to lock your script to the output format of an older Perforce release and facilitate seamless upgrades. This method *must* be called prior to calling `P4#connect`.

```
p4 = P4.new
p4.api_level = 57 # Lock to 2005.1 format
p4.connect
...
```

For the API integer levels that correspond to each Perforce release, see:

<http://kb.perforce.com/?article=512>

p4.api_level -> anInteger

Returns the current Perforce API compatibility level. Each iteration of the Perforce Server is given a level number. As part of the initial communication, the client protocol level is passed between client application and the Perforce Server. This value, defined in the Perforce API, determines the communication protocol level that the Perforce client will understand. All subsequent responses from the Perforce Server can be tailored to meet the requirements of that client protocol level.

For more information, see:

<http://kb.perforce.com/?article=512>

p4.at_exception_level(lev) { ... } -> self

Executes the associated block under a specific exception level. Returns to the previous exception level when the block returns.

```
p4 = P4.new
p4.client = "www"
p4.connect
p4.at_exception_level( P4::RAISE_ERRORS ) do
  p4.run_sync
end
p4.disconnect
```

p4.charset= aString -> aString

Sets the character set to use when connect to a Unicode enabled server. Do not use when working with non-Unicode-enabled servers. By default, the character set is the value of the P4CHARSET environment variable. If the character set is invalid, this method raises a P4Exception.

```
p4 = P4.new
p4.client = "www"
p4.charset = "iso8859-1"
p4.connect
p4.run_sync
p4.disconnect
```

p4.charset -> aString

Get the name of the character set in use when working with Unicode-enabled servers.

```
p4 = P4.new
p4.charset = "utf8"
puts( p4.charset )
```

p4.client= aString -> aString

Set the name of the client workspace you wish to use. If not called, defaults to the value of P4CLIENT taken from any P4CONFIG file present, or from the environment as per the usual Perforce convention. Must be called before connecting to the Perforce server.

```
p4 = P4.new
p4.client = "www"
p4.connect
p4.run_sync
p4.disconnect
```

p4.client -> aString

Get the name of the Perforce client currently in use

```
p4 = P4.new
puts( p4.client )
```

p4.connect -> aBool

Connect to the Perforce Server. You must connect before you can execute commands. Raises a `P4Exception` if the connection attempt fails.

```
p4 = P4.new
p4.connect
```

p4.connected? -> aBool

Test whether or not the session has been connected, and if the connection has not been dropped.

```
p4 = P4.new
p4.connected?
```

p4.cwd= aString -> aString

Sets the current working directory. Can be called prior to executing any Perforce command. Sometimes necessary if your script executes a `chdir()` as part of its processing.

```
p4 = P4.new
p4.cwd = "/home/tony"
```

p4.cwd -> aString

Get the current working directory

```
p4 = P4.new
puts( p4.cwd )
```

p4.delete_<spectype>([options], name) -> anArray

The delete methods are simply shortcut methods that allow you to quickly delete the definitions of clients, labels, branches, etc. These methods are equivalent to

```
p4.run( <spectype>, '-d', [options], <spec name> )
```

For example:

```
require "P4"
require "parsedate"
include ParseDate
now = Time.now
p4 = P4.new
begin
  p4.connect
  p4.run_clients.each do
    |client|
      atime = parsedate( client[ "Access" ] )
      if ( atime + 24 * 3600 * 365 ) < now )
        p4.delete_client( '-f', client[ "client" ] )
      end
    end
  end
rescue P4Exception
  p4.errors.each { |e| puts( e ) }
ensure
  p4.disconnect
end
```

p4.disconnect -> true

Disconnect from the Perforce Server.

```
p4 = P4.new
p4.connect
p4.disconnect
```

p4.errors -> anArray

Returns the array of errors which occurred during execution of the previous command.

```
p4 = P4.new
begin
  p4.connect
  p4.exception_level( P4::RAISE_ERRORS ) # ignore "File(s) up-to-date"
  files = p4.run_sync
rescue P4Exception
  p4.errors.each { |e| puts( e ) }
ensure
  p4.disconnect
end
```

p4.exception_level= anInteger -> anInteger

Configures the events which give rise to exceptions. The following three levels are supported:

- `P4::RAISE_NONE` disables all exception raising and makes the interface completely procedural.
- `P4::RAISE_ERRORS` causes exceptions to be raised only when errors are encountered.
- `P4::RAISE_ALL` causes exceptions to be raised for both errors and warnings. This is the default.

```
p4 = P4.new
p4.exception_level = P4::RAISE_ERRORS
p4.connect # P4Exception on failure
p4.run_sync # File(s) up-to-date is a warning so no exception is raised
p4.disconnect
```

p4.exception_level -> aNumber

Returns the current exception level.

p4.fetch_<spectype>([name]) -> aP4::Spec

The `fetch_spectype` methods are shortcut methods that allow you to quickly fetch the definitions of clients, labels, branches, etc. They're equivalent to:

```
p4.run( spectype, '-o', ... ).shift
```

For example:

```
p4 = P4.new
begin
  p4.connect
  client      = p4.fetch_client()
  other_client = p4.fetch_client( "other" )
  label       = p4.fetch_label( "somelabel" )
rescue P4Exception
  p4.errors.each { |e| puts( e ) }
ensure
  p4.disconnect
end
```

p4.format_spec(<spectype>, aHash)-> aString

Converts the fields in a hash containing the elements of a Perforce form (spec) into the string representation familiar to users.

The first argument is the type of spec to format: for example, `client`, `branch`, `label`, and so on. The second argument is the hash to parse.

There are shortcuts available for this method. You can use

```
p4.format_spectype( hash )
```

instead of

```
p4.format_spec( spectype, hash )
```

where *spectype* is the name of a Perforce spec, such as `client`, `label`, etc.

p4.format_<spectype> aHash -> aHash

The `format_spectype` methods are shortcut methods that allow you to quickly fetch the definitions of clients, labels, branches, etc. They're equivalent to:

```
p4.format_spec( spectype, aHash )
```

p4.host= aString -> aString

Set the name of the current host. If not called, defaults to the value of `P4HOST` taken from any `P4CONFIG` file present, or from the environment as per the usual Perforce convention. Must be called before connecting to the Perforce server.

```
p4 = P4.new
p4.host = "workstation123.perforce.com"
p4.connect
...
p4.disconnect
```

p4.host -> aString

Get the current hostname

```
p4 = P4.new
puts( p4.host )
```

p4.input= (aString|aHash|anArray) -> aString|aHash|anArray

Store input for the next command.

Call this method prior to running a command requiring input from the user. When the command requests input, the specified data will be supplied to the command. Typically, commands of the form `p4 cmd -i` are invoked using the `P4#save_spectype` methods, which call `P4#input()` internally; there is no need to call `P4#input` when using the `P4#save_spectype` shortcuts.

You may pass a string, a hash, or (for commands that take multiple inputs from the user) an array of strings or hashes. If you pass an array, note that the array will be shifted each time Perforce asks the user for input.

```
p4 = P4.new
p4.connect
change = p4.run_change( "-o" ).shift
change[ "Description" ] = "Autosubmitted changelist"
p4.input = change
p4.run_submit( "-i" )
p4.disconnect
```

p4.maxlocktime= anInteger -> anInteger

Limit the amount of time (in milliseconds) spent during data scans to prevent the server from locking tables for too long. Commands that take longer than the limit will be aborted. The limit remains in force until you disable it by setting it to zero. See `p4 help maxlocktime` for information on the commands that support this limit.

```
p4 = P4.new
begin
  p4.connect
  p4.maxlocktime = 10000 # 10 seconds
  files = p4.run_sync
rescue P4Exception => ex
  p4.errors.each { |e| $stderr.puts( e ) }
ensure
  p4.disconnect
end
```

p4.maxlocktime -> anInteger

Get the current maxlocktime setting

```
p4 = P4.new
puts( p4.maxlocktime )
```

p4.maxresults= anInteger -> anInteger

Limit the number of results Perforce permits for subsequent commands. Commands that produce more than this number of results will be aborted. The limit remains in force until

you disable it by setting it to zero. See `p4 help maxresults` for information on the commands that support this limit.

```
p4 = P4.new
begin
  p4.connect
  p4.maxresults = 100
  files = p4.run_sync
rescue P4Exception => ex
  p4.errors.each { |e| $stderr.puts( e ) }
ensure
  p4.disconnect
end
```

p4.maxresults -> anInteger

Get the current maxresults setting

```
p4 = P4.new
puts( p4.maxresults )
```

p4.maxscanrows= anInteger -> anInteger

Limit the number of database records Perforce will scan for subsequent commands. Commands that attempt to scan more than this number of records will be aborted. The limit remains in force until you disable it by setting it to zero. See `p4 help maxscanrows` for information on the commands that support this limit.

```
p4 = P4.new
begin
  p4.connect
  p4.maxscanrows = 100
  files = p4.run_sync
rescue P4Exception => ex
  p4.errors.each { |e| $stderr.puts( e ) }
ensure
  p4.disconnect
end
```

p4.maxscanrows -> anInteger

Get the current maxscanrows setting

```
p4 = P4.new
puts( p4.maxscanrows )
```

p4.p4config_file -> aString

Get the path to the current P4CONFIG file

```
p4 = P4.new
puts( p4.p4config_file )
```

p4.parse_<spectype> (aString) -> aP4::Spec

This is equivalent to `parse_spec(spectype, aString)`.

p4.parse_spec(<spectype>, aString) -> aP4::Spec

Parses a Perforce form (spec) in text form into a Ruby hash using the spec definition obtained from the server.

The first argument is the type of spec to parse: "client", "branch", "label", and so on. The second argument is the string buffer to parse.

Note that there are shortcuts available for this method. You can use:

```
p4.parse_spectype( buf )
```

instead of

```
p4.parse_spec( spectype, buf )
```

Where *spectype* is one of `client`, `branch`, `label`, and so on.

p4.password= aString -> aString

Set your Perforce password, in plain text. If not used, takes the value of `P4PASSWD` from any `P4CONFIG` file in effect, or from the environment according to the normal Perforce conventions. This password will also be used if you later call `p4.run_login` to login using the 2003.2 and later ticket system.

```
p4 = P4.new
p4.password = "mypass"
p4.connect
p4.run_login
```

p4.password -> aString

Get the current password or ticket. This may be the password in plain text, or if you've used `p4.run_login`, it'll be the value of the ticket you've been allocated by the server.

```
p4 = P4.new
puts( p4.password )
```

p4.port= aString -> aString

Set the host and port of the Perforce server you want to connect to. If not called, defaults to the value of `P4PORT` in any `P4CONFIG` file in effect, and then to the value of `P4PORT` taken from the environment.

```
p4 = P4.new
p4.port = "localhost:1666"
p4.connect
...
p4.disconnect
```

p4.port -> aString

Get the host and port of the current Perforce server.

```
p4 = P4.new
puts( p4.port )
```

p4.prog= aString -> aString

Set the name of the program, as reported to Perforce system administrators running `p4 monitor show -e` in Perforce 2004.2 or later releases.

```
p4 = P4.new
p4.prog = "sync-script"
p4.connect
...
p4.disconnect
```

p4.prog -> aString

Get the name of the program as reported to the Perforce Server.

```
p4 = P4.new
p4.prog = "sync-script"
puts( p4.prog )
```

p4.run_cmd(arguments) -> anArray

This is equivalent to `p4.run (cmd, arguments...)`.

p4.run(aCommand, arguments...) -> anArray

Base interface to all the run methods in this API. Runs the specified Perforce command with the arguments supplied. Arguments may be in any form as long as they can be converted to strings by `to_s`.

The `p4.run` method returns an array of results whether the command succeeds or fails; the array may, however, be empty. Whether the elements of the array are strings or

hashes depends on (a) server support for tagged output for the command, and (b) whether tagged output was disabled by calling `p4.tagged = false`.

In the event of errors or warnings, and depending on the exception level in force at the time, run will raise a `P4Exception`. If the current exception level is below the threshold for the error/warning, run returns the output as normal and the caller must explicitly review `p4.errors` and `p4.warnings` to check for errors or warnings.

```
p4 = P4.new
p4.connect
spec = p4.run( "client", "-o" ).shift
p4.disconnect
```

Shortcuts are available for `p4.run`. For example,

```
p4.run_command( args )
```

is equivalent to:

```
p4.run( "command", args )
```

There are also some shortcuts for common commands such as editing Perforce forms and submitting. Consequently, this:

```
p4 = P4.new
p4.connect
clientspec = p4.run_client( "-o" ).shift
clientspec[ "Description" ] = "Build client"
p4.input( clientspec )
p4.run_client( "-i" )
p4.disconnect
```

...may be shortened to

```
p4 = P4.new
p4.connect
clientspec = p4.fetch_client
clientspec[ "Description" ] = "Build client"
p4.save_client( clientspec )
p4.disconnect
```

The following are equivalent:

<code>p4.delete_spectype</code>	<code>p4.run("spectype", "-d ")</code>
<code>p4.fetch_spectype</code>	<code>p4.run("spectype", "-o ").shift</code>
<code>p4.save_spectype(spec)</code>	<code>p4.input = spec</code>
	<code>p4.run("spectype", "-i")</code>

As the commands associated with `fetch_spectype` typically return only one item, these methods do not return an array, but instead return the first result element.

For convenience in submitting changelists, changes returned by `fetch_change()` can be passed to `run_submit`. For example:

```
p4 = P4.new
p4.connect
spec = p4.fetch_change
spec[ "Description" ] = "Automated change"
p4.run_submit( spec )
p4.disconnect
```

p4.run_filelog(fileSpec) -> anArray

Runs a `p4 filelog` on the `fileSpec` provided and returns an array of `P4::DepotFile` results when executed in tagged mode, and an array of strings when executed in non-tagged mode. By default, the raw output of `p4 filelog` is tagged; this method restructures the output into a more user-friendly (and object-oriented) form.

```
p4 = P4.new
begin
  p4.connect
  p4.run_filelog( "index.html" ).shift.each_revision do
    |r|
      r.each_integration do
        |i|
          # Do something
      end
    end
  end
rescue P4Exception
  p4.errors.each { |e| puts( e ) }
ensure
  p4.disconnect
end
```

p4.run_login(arg...) -> anArray

Runs `p4 login` using a password (or other arguments) set by the user.

p4.run_password(oldpass, newpass) -> anArray

A thin wrapper to make it easy to change your password. This method is (literally) equivalent to the following code:

```
p4.input( [ oldpass, newpass, newpass ] )
p4.run( "password" )
```

For example:

```
p4 = P4.new
p4.password = "myoldpass"
begin
  p4.connect
  p4.run_password( "myoldpass", "mynewpass" )
rescue P4Exception
  p4.errors.each { |e| puts( e ) }
ensure
  p4.disconnect
end
```

p4.run_resolve(args) [block] -> anArray

Interface to p4 resolve. Without a block, simply runs a non-interactive resolve (typically an automatic resolve).

```
p4.run_resolve( "-at" )
```

When a block is supplied, the block is invoked once for each merge scheduled by Perforce. For each merge, a `P4::MergeData` object is passed to the block. This object contains the context of the merge.

The block determines the outcome of the merge by evaluating to one of the following strings:

Block string	Meaning
ay	Accept Yours
at	Accept Theirs
am	Accept Merge result
ae	Accept Edited result
s	Skip this merge
q	Abort the merge

For example:

```
p4.run_resolve() do
  |md|
  puts( "Merging..." )
  puts( "Yours: #{md.your_name}" )
  puts( "Theirs: #{md.their_name}" )
  puts( "Base: #{md.base_name}" )
  puts( "Yours file: #{md.your_path}" )
  puts( "Theirs file: #{md.their_path}" )
  puts( "Base file: #{md.base_path}" )
  puts( "Result file: #{md.result_path}" )
  puts( "Merge Hint: #{md.merge_hint}" )

  result = md.merge_hint
  if( result == "e" )
    puts( "Invoking external merge application" )
    result = "s" # If the merge doesn't work, we'll skip
    result = "am" if md.run_merge()
  end
  result
end
```

p4.run_submit([aHash], [arg...]) -> anArray

Submit a changelist to the server. To submit a changelist, set the fields of the changelist as required and supply any flags:

```
change = p4.fetch_change
change._description = "Some description"
p4.run_submit( "-r", change )
```

You can also submit a changelist by supplying the arguments as you would on the command line:

```
p4.run_submit( "-d", "Some description", "somedir/..." )
```

p4.save_<spectype>([options], hashOrString) -> anArray

The `save_spectype` methods are shortcut methods that allow you to quickly update the definitions of clients, labels, branches, etc. They are equivalent to:

```
p4.input = hashOrString
p4.run( spectype, "-i" )
```

For example:

```
p4 = P4.new
begin
  p4.connect
  client      = p4.fetch_client()
  client[ "Owner" ] = p4.user
  p4.save_client( client )
rescue P4Exception
  p4.errors.each { |e| puts( e ) }
ensure
  p4.disconnect
end
```

p4.server_level -> anInteger

Returns the current Perforce server level. Each iteration of the Perforce Server is given a level number. As part of the initial communication this value is passed between the client application and the Perforce Server. This value is used to determine the communication that the Perforce Server will understand. All subsequent requests can therefore be tailored to meet the requirements of this Server level.

For more information, see:

<http://kb.perforce.com/?article=571>

p4.tagged= aBool -> aBool

Toggles tagged output. By default, tagged output is on.

```
p4 = P4.new
p4.tagged = false
```

p4.tagged? -> aBool

Detects whether or not you are in tagged mode.

```
p4 = P4.new
puts ( p4.tagged? )
p4.tagged = false
puts ( p4.tagged? )
```

p4.ticketfile= aString -> aString

Sets the location of the P4TICKETS file

```
p4 = P4.new
p4.ticketfile = "/home/tony/tickets"
```

p4.ticketfile -> aString

Get the path to the current P4TICKETS file.

```
p4 = P4.new
puts( p4.ticketfile )
p4.ticketfile = "/home/tony/tickets"
```

p4.user= aString -> aString

Set the Perforce username. If not called, defaults to the value of P4USER taken from any P4CONFIG file present, or from the environment as per the usual Perforce convention. Must be called before connecting to the Perforce server.

```
p4 = P4.new
p4.user = "tony"
p4.connect
...
p4.disconnect
```

p4.user -> aString

Returns the current Perforce username

```
p4 = P4.new
puts( p4.user )
```

p4.version= aString -> aString

Set the version of your script, as reported to the Perforce Server.

p4.version -> aString

Get the version of your script, as reported to the Perforce Server.

p4.warnings -> anArray

Returns the array of warnings which arose during execution of the last command.

```
p4 = P4.new
begin
  p4.connect
  p4.exception_level( P4::RAISE_ALL ) # File(s) up-to-date is a warning
  files = p4.run_sync
rescue P4Exception => ex
  p4.warnings.each { |w| puts( w ) }
ensure
  p4.disconnect
end
```

Class P4Exception

Shallow subclass of `RuntimeError` to be used for catching Perforce specific errors. Doesn't contain any extra information. See `P4#errors` and `P4#warnings` for details of the errors giving rise to the exception.

Class Methods

None.

Instance Methods

None.

Class P4::DepotFile

Description

Utility class providing easy access to the attributes of a file in a Perforce depot. Each `P4::DepotFile` object contains summary information about the file, and a list of revisions (`P4::Revision` objects) of that file. Currently, only the `P4#run_filelog` method returns an array of `P4::DepotFile` objects.

Class Methods

None

Instance Methods

`df.depot_file -> aString`

Returns the name of the depot file to which this object refers.

`df.each_revision { |rev| block } -> revArray`

Iterates over each revision of the depot file

`df.revisions -> aArray`

Returns an array of revisions of the depot file

Class P4::Revision

Description

Utility class providing easy access to the revisions of a file in a Perforce depot. `P4::Revision` objects can store basic information about revisions and a list of the integrations for that revision. Created by `run_filelog`.

Class Methods

None

Instance Methods

rev.action -> aString

Returns the name of the action which gave rise to this revision of the file.

rev.change -> aNumber

Returns the change number that gave rise to this revision of the file.

rev.client -> aString

Returns the name of the client from which this revision was submitted.

rev.depot_file -> aString

Returns the name of the depot file to which this object refers.

rev.desc -> aString

Returns the description of the change which created this revision. Note that only the first 31 characters are returned unless you use `p4 filelog -L` for the first 250 characters, or `p4 filelog -l` for the full text.

rev.digest -> aString

Returns the MD5 digest for this revision of the file.

rev.each_integration { |integ| block } -> integArray

Iterates over each the integration records for this revision of the depot file.

rev.filesize -> aNumber

Returns size of this revision.

rev.integrations -> integArray

Returns the list of integrations for this revision.

rev.revno -> aNumber

Returns the number of this revision of the file.

rev.time -> aTime

Returns the date/time that this revision was created.

rev.type -> aString

Returns this revision's Perforce filetype.

rev.user -> aString

Returns the name of the user who created this revision.

Class P4::Integration

Description

Utility class providing easy access to the details of an integration record. Created by `run_filelog`.

Class Methods

None.

Instance Methods

integ.how -> aString

Returns the type of the integration record - how that record was created.

integ.file -> aPath

Returns the path to the file being integrated to/from.

integ.srev -> aNumber

Returns the start revision number used for this integration.

integ.erev -> aNumber

Returns the end revision number used for this integration.

Class P4::MergeData

Description

Class containing the context for an individual merge during execution of a `p4 resolve`.

Class Methods

None

Instance Methods

md.your_name() -> aString

Returns the name of “your” file in the merge. This is typically a path to a file in the workspace.

```
p4.run_resolve() do
  |md|
  yours = md.your_name
  md.merge_hint # merge result
end
```

md.their_name() -> aString

Returns the name of “their” file in the merge. This is typically a path to a file in the depot.

```
p4.run_resolve() do
  |md|
  theirs = md.their_name
  md.merge_hint # merge result
end
```

md.base_name() -> aString

Returns the name of the “base” file in the merge. This is typically a path to a file in the depot.

```
p4.run_resolve() do
  |md|
  base = md.base_name
  md.merge_hint # merge result
end
```

md.your_path() -> aString

Returns the path of “your” file in the merge. This is typically a path to a file in the workspace.

```
p4.run_resolve() do
  |md|
    your_path = md.your_path
    md.merge_hint # merge result
end
```

md.their_path() -> aString

Returns the path of “their” file in the merge. This is typically a path to a temporary file on your local machine in which the contents of `their_name()` have been loaded.

```
p4.run_resolve() do
  |md|
    their_name = md.their_name
    their_file = File.open( md.their_path )
    md.merge_hint # merge result
end
```

md.base_path() -> aString

Returns the path of the base file in the merge. This is typically a path to a temporary file on your local machine in which the contents of `base_name()` have been loaded.

```
p4.run_resolve() do
  |md|
    base_name = md.base_name
    base_file = File.open( md.base_path )
    md.merge_hint # merge result
end
```

md.result_path() -> aString

Returns the path to the merge result. This is typically a path to a temporary file on your local machine in which the contents of the automatic merge performed by the server have been loaded.

```
p4.run_resolve() do
  |md|
    result_file = File.open( md.result_path )
    md.merge_hint # merge result
end
```

md.merge_hint() -> aString

Returns the hint from the server as to how it thinks you might best resolve this merge.

```
p4.run_resolve() do
  |md|
  puts ( md.merge_hint ) # merge result
end
```

md.run_merge() -> aBool

If the environment variable P4MERGE is defined, run_merge() invokes the specified program and returns a boolean based on the return value of that program.

```
p4.run_resolve() do
  |md|
  if ( md.run_merge() )
    "am"
  else
    "s"
  end
end
```

Class P4::Spec

Description

The `P4::Spec` class is a hash containing key/value pairs for all the fields in a Perforce form. It provides two things over and above its parent class (`Hash`):

- Fieldname validation. Only valid field names may be set in a `P4::Spec` object. Note that only the field name is validated, not the content.
- Accessor methods for easy access to the fields

Class Methods

`new P4::Spec.new(anArray) -> aP4::Spec`

Constructs a new `P4::Spec` object given an array of valid fieldnames.

Instance Methods

`spec._<fieldname> -> aValue`

Returns the value associated with the field named `<fieldname>`. This is equivalent to `spec["<fieldname>"]` with the exception that when used as a method, the fieldnames may be in lowercase regardless of the actual case of the fieldname.

```
client = p4.fetch_client()
root   = client._root
desc   = client._description
```

`spec._<fieldname>= aValue -> aValue`

Updates the value of the named field in the spec. Raises a `P4Exception` if the fieldname is not valid for specs of this type.

```
client = p4.fetch_client()
client._root      = "/home/tony/new-client"
client._description = "My new client spec"
p4.save_client( client )
```

spec.permitted_fields -> anArray

Returns an array containing the names of fields that are valid in this spec object. This does not imply that values for all of these fields are actually set in this object, merely that you may choose to set values for any of these fields if you want to.

```
client = p4.fetch_client()
spec.permitted_fields.each do
  | field |
    printf ( "%14s = %s\n", field, client[ field ] )
end
```

Introduction

P4Perl is a Perl module that provides an object-oriented API to the Perforce SCM system. Using P4Perl is faster than using the command-line interface in scripts, because multiple command can be executed on a single connection, and because it returns the Perforce Server's responses as Perl hashes and arrays.

The main features are:

- Get Perforce data and forms in hashes and arrays
- Edit Perforce forms by modifying hashes
- Run as many commands on a connection as required
- The output of commands is returned as a Perl array
- The elements of the array returned are strings or, where appropriate, hash references

System Requirements

P4Perl is supported on Windows, Linux, Solaris, and FreeBSD. To build P4Perl, your development machine must also have:

- Perl 5.8.8 (ActivePerl on Windows) development files
- `make` (or `nmake` on Windows)
- The 2007.3 Perforce C/C++ API for your target platform
- The same C++ compiler used to build the Perforce C++ API on your target platform.

(If you get “unresolved symbol” errors when building or running P4Perl, you probably used the wrong compiler or the wrong Perforce API build.)

Installing P4Perl

Download P4Perl from the Perforce web site downloads page. After downloading, you can either run the installer or build the interface from source, as described in the release notes.

Programming with P4Perl

The following example shows how to connect to a Perforce server, run a `p4 info` command, and open a file for edit.

```
use P4;
my $p4 = new P4;
$p4->SetClient( $clientname );
$p4->SetPort ( $p4port );
$p4->SetPassword( $p4password );
$p4->Connect() or die( "Failed to connect to Perforce Server" );

my $info = $p4->Run( "info" );
$p4->Edit( "file.txt" ) or die( "Failed to edit file.txt" );
$p4->Disconnect();
```

P4Perl Classes

The P4 module consists of several public classes:

- P4
- P4::DepotFile
- P4::Revision
- P4::Integration

The following tables provide brief details about each public class.

P4

The main class used for executing Perforce commands. Almost everything you do with P4Perl will involve this class.

Method	Description
<code>new()</code>	Construct a new P4 object.
<code>Identify()</code>	Print build information including P4Perl version and Perforce API version.
<code>Connect()</code>	Initialize the Perforce client and connect to the Server.

Method	Description
<code>new()</code>	Construct a new P4 object.
<code>Identify()</code>	Print build information including P4Perl version and Perforce API version.
<code>Connect()</code>	Initialize the Perforce client and connect to the Server.
<code>Disconnect()</code>	Disconnect from the Perforce Server
<code>ErrorCount()</code>	Returns the number of errors encountered during execution of the last command
<code>Errors()</code>	Returns a list of the error messages received during execution of the last command.
<code>Fetch<spectype>()</code>	Shorthand for running <code>\$p4->Run("spectype", "-o")</code>
<code>Format<spectype>()</code>	Shorthand for running <code>\$p4->FormatSpec(<spectype>, hash)</code>
<code>FormatSpec()</code>	Converts a Perforce form of the specified type (client/label etc.) held in the supplied hash into its string representation.

Method	Description
<code>GetCharset()</code>	Get character set when connecting to Unicode servers
<code>GetClient()</code>	Get current client workspace (<code>P4CLIENT</code>)
<code>GetCwd()</code>	Get current working directory
<code>GetHost()</code>	Get the current hostname
<code>GetMaxLockTime()</code>	Get <code>MaxLockTime</code> used for all following commands
<code>GetMaxResults()</code>	Get <code>MaxResults</code> used for all following commands
<code>GetMaxScanRows()</code>	Get <code>MaxScanRows</code> used for all following commands
<code>GetPassword()</code>	Get the current password or ticket.
<code>GetPort()</code>	Set host and port (<code>P4PORT</code>)
<code>GetProg()</code>	Get the program name as shown by <code>p4 monitor show -e</code>
<code>GetUser()</code>	Get the current username (<code>P4PORT</code>)
<code>GetVersion()</code>	Get the version of your script, as reported to the Perforce Server.
<code>IsConnected()</code>	Test whether or not session has been connected and/or has been dropped
<code>IsTagged()</code>	Detects whether or not tagged output is enabled.
<code>P4ConfigFile()</code>	Get the location of the configuration file used (<code>P4CONFIG</code>).
<code>Parse<Spectype>()</code>	Shorthand for running <code>\$p4-ParseSpec(<spectype>, buffer)</code>
<code>ParseSpec()</code>	Converts a Perforce form of the specified type (client/label etc.) held in the supplied string into a hash and returns a reference to that hash.
<code>Run<cmd>()</code>	Shorthand for running <code>\$p4-Run (cmd, arg, ...)</code>
<code>Run()</code>	Run a Perforce command and return its results. Check for errors with <code>P4::ErrorCount()</code>
<code>RunFileLog()</code>	Runs a <code>p4 filelog</code> on the <code>fileSpec</code> provided and returns an array of <code>P4::DepotFile</code> objects
<code>RunLogin()</code>	Runs <code>p4 login</code> using a password (or other arguments) set by the user.
<code>RunPassword()</code>	A thin wrapper for changing your password.
<code>RunSubmit()</code>	Submit a changelist to the server.

Method	Description
Save<Spectype>()	Shorthand for \$p4->SetInput(\$spectype); \$p4->Run("spectype", "-i");
ServerLevel()	Returns an integer specifying the server protocol level.
SetApiLevel()	Specify the API compatibility level to use for this script.
SetCharset()	Set character set when connecting to Unicode servers
SetClient()	Set current client workspace (P4CLIENT)
SetCwd()	Set current working directory
SetHost()	Set the name of the current host (P4HOST)
SetInput()	Save the supplied argument as input to be supplied to a subsequent command.
SetMaxLockTime()	Set MaxLockTime used for all following commands
SetMaxResults()	Set MaxResults used for all following commands
SetMaxScanRows()	Set MaxScanRows used for all following commands
SetPassword()	Set Perforce password (P4PASSWD)
SetPort()	Set host and port (P4PORT)
SetProg()	Set the program name as shown by p4 monitor show -e
SetUser()	Set the Perforce username (P4USER)
SetVersion()	Set the version of your script, as reported to the Perforce Server.
Tagged()	Toggles tagged output (1 or 0). By default, tagged output is on (1).
TicketFile()	Get or set the location of the P4TICKETS file
WarningCount()	Returns the number of warnings issued by the last command
Warnings()	Returns a list of warnings from the last command.

P4::DepotFile

Utility class allowing access to the attributes of a file in the depot. Returned by P4::RunFileLog.

Method	Description
DepotFile()	Name of the depot file to which this object refers
Revisions()	Returns an array of revision objects for the depot file

P4::Revision

Utility class allowing access to the attributes of a revision of a file in the depot. Returned by `P4::RunFileLog`.

Method	Description
<code>Change()</code>	Returns the changelist number that gave rise to this revision of the file.
<code>Client()</code>	Returns the name of the client from which this revision was submitted.
<code>Desc()</code>	Returns the description of the change which created this revision.
<code>DepotFile()</code>	Returns the name of the depot file to which this object refers.
<code>Digest()</code>	Returns the MD5 digest for this revision.
<code>FileSize()</code>	Returns the size of this revision.
<code>Rev()</code>	Returns the number of this revision.
<code>Time()</code>	Returns date/time this revision was created.
<code>Type()</code>	Returns the Perforce filetype of this revision.
<code>User()</code>	Returns the name of the user who created this revision.

P4::Integration

Utility class allowing access to the attributes of an integration record for a revision of a file in the depot. Returned by `P4::RunFileLog`.

Method	Description
<code>How()</code>	Integration method (merge/branch/copy/ignored)
<code>File()</code>	Integrated file
<code>SRev()</code>	End revision
<code>ERev()</code>	Start revision

Class P4

Description

Main interface to the Perforce client API.

This module provides an object-oriented interface to the Perforce SCM system. Data is returned in Perl arrays and hashes and input can also be supplied in these formats.

Each `P4` object represents a connection to the Perforce Server, and multiple commands may be executed (serially) over a single connection.

The basic model is to:

1. Instantiate your `P4` object
2. Specify your Perforce client environment
 - `SetClient`
 - `SetHost`
 - `SetPassword`
 - `SetPort`
 - `SetUser`
3. Connect to the Perforce Server
4. Run your Perforce commands
5. Disconnect from the Perforce Server

Base methods

`P4::new()` -> `P4`

Construct a new `P4` object. For example:

```
my $p4 = new P4;
```

`P4::Identify()` -> `string`

Print build information including `P4Perl` version and Perforce API version.

```
print P4::Identify();
```

`P4::Connect()` -> `bool`

Initializes the Perforce client and connects to the server. Returns false on failure and true on success.

P4::Disconnect() -> undef

Terminate the connection and clean up. Should be called before exiting.

P4::ErrorCount() -> integer

Returns the number of errors encountered during execution of the last command

P4::Errors() -> list

Returns a list of the error messages received during execution of the last command.

P4::Fetch<spectype>([name]) -> hashref

Shorthand for running `$p4->Run("spectype", "-o")` and returning the first element of the result array. For example:

```
$label      = $p4->FetchLabel( $labelname );
$change     = $p4->FetchChange( $changenno );
$clientspec = $p4->FetchClient( $clientname );
```

P4::Format<spectype>(hash) -> string

Shorthand for running `$p4->FormatSpec(<spectype>, hash)` and returning the results. For example:

```
$change     = $p4->FetchChange();
$change->{ 'Description' } = 'Some description';
$form       = $p4->FormatChange( $change );
printf( "Submitting this change:\n\n%s\n", $form );
$p4->SubmitSpec( $change );
```

P4::FormatSpec(\$spectype, \$string) -> string

Converts a Perforce form of the specified type (client/label etc.) held in the supplied hash into its string representation. Shortcut methods are available that obviate the need to supply the type argument. The following two examples are equivalent:

```
my $client = $p4->FormatSpec( "client", $hash );
my $client = $p4->FormatClient( $hash );
```

P4::GetCharset() -> string

Return the name of the current charset in use. Applicable only when used with Perforce servers running in unicode mode.

P4::GetClient() -> string

Returns the current Perforce client name. This may have previously been set by `SetClient()`, or may be taken from the environment or `P4CONFIG` file if any. If all that fails, it will be your hostname.

P4::GetCwd() -> string

Returns the current working directory as your Perforce client sees it.

P4::GetHost() -> string

Returns the client hostname. Defaults to your hostname, but can be overridden with `SetHost()`

P4::GetMaxLockTime(\$value) -> integer

Get the current `maxlocktime` setting.

P4::GetMaxResults(\$value) -> integer

Get the current `maxresults` setting.

P4::GetMaxScanRows(\$value) -> integer

Get the current `maxscanrows` setting.

P4::GetPassword() -> string

Returns your Perforce password. Taken from a previous call to `SetPassword()` or extracted from the environment (`$ENV{P4PASSWD}`), or a `P4CONFIG` file.

P4::GetPort() -> string

Returns the current address for your Perforce server. Taken from a previous call to `SetPort()`, or from `$ENV{P4PORT}` or a `P4CONFIG` file.

P4::GetProg() -> string

Get the name of the program as reported to the Perforce Server.

P4::GetUser() -> String

Get the current user name. Taken from a previous call to `SetUser()`, or from `$ENV{P4USER}` or a `P4CONFIG` file.

P4::GetVersion (\$string) -> string

Get the version of your script, as reported to the Perforce Server.

P4::IsConnected() -> bool

Returns true if the session has been connected, and has not been dropped.

P4::IsTagged() -> bool

Returns true if Tagged mode is enabled on this client.

P4::P4ConfigFile() -> string

Get the path to the current `P4CONFIG` file.

P4::Parse<Spectype>(\$string) -> hashref

Shorthand for running `$p4->ParseSpec(<spectype>, buffer)` and returning the results. For example:

```
$p4 = new P4;
$p4->Connect() or die( "Failed to connect to server" );
$client = $p4->FetchClient();           # Returns a hashref
$client = $p4->FormatClient( $client ); # Convert to string
$client = $p4->ParseClient( $client );  # Convert back to hashref
```

P4::ParseSpec(\$spectype, \$string) -> hashref

Converts a Perforce form of the specified type (client/label etc.) held in the supplied string into a hash and returns a reference to that hash. Shortcut methods are available to avoid the need to supply the type argument. The following two examples are equivalent:

```
my $hash = $p4->ParseSpec( "client", $clientspec );
my $hash = $p4->ParseClient( $clientspec );
```

P4::Run<cmd>([\$arg...]) -> list | arrayref

Shorthand for running `$p4->Run (cmd, arg, ...)` and returning the results.

P4::Run(cmd, [\$arg...]) -> list | arrayref

Run a Perforce command and return its results. Because Perforce commands can partially succeed and partially fail, it is good practice to check for errors using `P4::ErrorCount()`.

Results are returned as follows:

- A list of results in array context
- An array reference in scalar context

The AutoLoader enables you to treat Perforce commands as methods:

```
p4->Edit( "filename.txt" );
```

is equivalent to

```
$p4->Run( "edit", "filename.txt" );
```

Note that the content of the array of results you get depends on (a) whether you're using tagged mode, (b) the command you've executed, (c) the arguments you supplied, and (d) your Perforce server version.

Tagged mode and form parsing mode are turned on by default; each result element is a hashref, but this is dependent on the command you ran and your server version.

In non-tagged mode, each result element is a string. In this case, because the Perforce server sometimes asks the client to write a blank line between result elements, some of these result elements can be empty.

Note that the return values of individual Perforce commands are not documented because they may vary between server releases.

To correlate the results returned by the P4 interface with those sent to the command line client, try running your command with RPC tracing enabled. For example:

Tagged mode

```
p4 -Ztag -vrpc=1 describe -s 4321
```

Non-Tagged mode

```
p4 -vrpc=1 describe -s 4321
```

Pay attention to the calls to `client-FstatInfo()`, `client-OutputText()`, `client-OutputData()` and `client-HandleError()`. Each call to one of these functions results in either a result element, or an error element.

P4::RunFileLog ([\$args ...], \$fileSpec ...) -> list | arrayref

Runs a `p4 filelog` on the `fileSpec` provided and returns an array of `P4::DepotFile` objects when executed in tagged mode.

P4::RunLogin (...) -> list | arrayref

Runs `p4 login` using a password (or other arguments) set by the user.

P4::RunPassword (\$oldpass, \$newpass) -> list | arrayref

A thin wrapper for changing your password from `$oldpass` to `$newpass`. Not to be confused with `P4::SetPassword`.

P4::RunSubmit (\$arg | \$hashref, ...) -> list | arrayref

Submit a changelist to the server. To submit a changelist, set the fields of the changelist as required and supply any flags:

```
$change = $p4->FetchChange();  
$change->{ 'Description' } = "Some description";  
$p4->RunSubmit( "-r", $change );
```

You can also submit a changelist by supplying the arguments as you would on the command line:

```
$p4->RunSubmit( "-d", "Some description", "somedir/..." );
```

P4::Save<Spectype>() -> list | arrayref

Shorthand for:

```
$p4->SetInput( $spectype );  
$p4->Run( "spectype", "-i");
```

For example:

```
$p4->SaveLabel( $label );  
$p4->SaveChange( $changenos );  
$p4->SaveClient( $clientspec );
```

P4::ServerLevel() -> integer

Returns an integer specifying the server protocol level. This is not the same as, but is closely aligned to, the server version. To find out your server's protocol level, run `p4 -vrpc=5 info` and look for the `server2` protocol variable in the output.

For more information, see:

<http://kb.perforce.com/?article=571>

Must be called after running a command.

P4::SetApiLevel(\$integer) -> undef

Specify the API compatibility level to use for this script. This is useful when you want your script to continue to work on newer server versions, even if the new server adds tagged output to previously unsupported commands.

The additional tagged output support can change the server's output, and confound your scripts. Setting the API level to a specific value allows you to lock the output to an older format, thus increasing the compatibility of your script.

Must be called before calling `P4::Connect()`. For example:

```
$p4->SetApiLevel( 57 ); # Lock to 2005.1 format  
$p4->Connect() or die( "Failed to connect to Perforce" );  
etc.
```

P4::SetCharset(\$charset) -> undef

Specify the character set to use for local files when used with a Perforce server running in unicode mode. Do not use unless your Perforce server is in unicode mode. Must be called before calling `P4::Connect()`. For example:

```
$p4->SetCharset( "winansi" );  
$p4->SetCharset( "iso8859-1" );  
$p4->SetCharset( "utf8" );  
etc.
```

P4::SetClient(\$client) -> undef

Sets the name of your Perforce client workspace. If you don't call this method, then the client workspace name will default according to the normal Perforce conventions:

1. Value from file specified by `P4CONFIG`
2. Value from `$ENV{P4CLIENT}`
3. Hostname

P4::SetCwd(\$path) -> undef

Sets the current working directory for the client.

P4::SetHost(\$hostname) -> undef

Sets the name of the client host, overriding the actual hostname. This is equivalent to `p4 -H hostname`, and only useful when you want to run commands as if you were on another machine.

P4::SetInput(\$string | \$hashref | \$arrayref) -> undef

Save the supplied argument as input to be supplied to a subsequent command. The input may be a hashref, a scalar string, or an array of hashrefs or scalar strings. If you pass an array, the array will be shifted once each time the Perforce command being executed asks for user input.

P4::SetMaxLockTime(\$integer) -> undef

Limit the amount of time (in milliseconds) spent during data scans to prevent the server from locking tables for too long. Commands that take longer than the limit will be aborted. The limit remains in force until you disable it by setting it to zero. See `p4 help maxresults` for information on the commands that support this limit.

P4::SetMaxResults(\$integer) -> undef

Limit the number of results for subsequent commands to the value specified. Perforce will abort the command if continuing would produce more than this number of results. Once set, this limit remains in force unless you remove the restriction by setting it to a value of 0.

P4::SetMaxScanRows(\$integer) -> undef

Limit the number of records Perforce will scan when processing subsequent commands to the value specified. Perforce will abort the command once this number of records has been scanned. Once set, this limit remains in force unless you remove the restriction by setting it to a value of 0.

P4::SetPassword(\$password) -> undef

Specify the password to use when authenticating this user against the Perforce Server - overrides all defaults. Not to be confused with `P4::Password()`.

P4::SetPort(\$port) -> undef

Set the port on which your Perforce server is listening. Defaults to:

1. Value from file specified by `P4CONFIG`
2. Value from `$ENV{P4PORT}`
3. `perforce:1666`

P4::SetProg(\$program_name) -> undef

Set the name of your script. This value is displayed in the server log on 2004.2 or later servers.

P4::SetUser(\$username) -> undef

Set your Perforce username. Defaults to:

1. Value from file specified by `P4CONFIG`
2. Value from `C<$ENV{P4USER}>`
3. OS username

P4::SetVersion (\$version) -> undef

Specify the version of your script, as recorded in the Perforce server log file.

P4::Tagged(0 | 1) -> undef

Enable (1) or disable (0) tagged output from the server. By default, tagged output is enabled, but can be disabled (or re-enabled) by calling this method.

When running in tagged mode, responses from commands that support tagged output will be returned in the form of a hashref.

When running in non-tagged mode, responses from commands are returned in the form of strings (that is, in plain text).

P4::TicketFile([\$string]) -> string

If called with an argument, set the path to the current `P4TICKETS` file (and return it). If called without arguments, return the path of the current `P4TICKETS` file.

P4::WarningCount() -> integer

Returns the number of warnings issued by the last command.

```
$p4->WarningCount();
```

P4::Warnings() -> list

Returns a list of warnings from the last command

```
$p4->Warnings();
```

Class P4::DepotFile

Description

P4::DepotFile objects are used to present information about files in the Perforce repository. They are returned by P4::RunFileLog.

Class Methods

None

Instance Methods

\$df->DepotFile() -> string

Returns the name of the depot file to which this object refers.

\$df->Revisions() -> array

Returns an array of P4::Revision objects, one for each revision of the depot file

Class P4::Revision

Description

P4::Revision objects represent individual revisions of files in the Perforce repository. They are returned as part of the output of P4::RunFileLog.

Class Methods

\$rev->Integrations() -> array

Returns an array of P4::Integration objects representing all integration records for this revision.

Instance Methods

\$rev->Change() -> integer

Returns the changelist number that gave rise to this revision of the file.

\$rev->Client() -> string

Returns the name of the client from which this revision was submitted.

\$rev->DepotFile() -> string

Returns the name of the depot file to which this object refers.

\$rev->Desc() -> string

Returns the description of the change which created this revision. Note that only the first 31 characters are returned unless you use `p4 filelog -L` for the first 250 characters, or `p4 filelog -l` for the full text.

\$rev->Digest() -> string

Returns the MD5 digest for this revision.

\$rev->FileSize() -> string

Returns the size of this revision.

\$rev->Rev() -> integer

Returns the number of this revision of the file.

\$rev->Time() -> string

Returns the date/time that this revision was created.

\$rev->Type() -> string

Returns this revision's Perforce filetype.

\$rev->User()

Returns the name of the user who created this revision.

Class P4::Integration

Description

`P4::Integration` objects represent Perforce integration records. They are returned as part of the output of `P4::RunFileLog`.

Class Methods

None

Instance Methods

`$integ->How() -> string`

Returns the type of the integration record - how that record was created.

`$integ->File() -> string`

Returns the path to the file being integrated to/from.

`$integ->SRev() -> integer`

Returns the start revision number used for this integration.

`$integ->ERev() -> integer`

Returns the end revision number used for this integration.

Introduction

P4Python, the Python interface to the Perforce API , enables you to write Python code that interacts with a Perforce server. P4Python enables your Python scripts to:

- Get Perforce data and forms in dictionaries and lists
- Edit Perforce forms by modifying dictionaries
- Provide exception-based error handling and optionally ignore warnings
- Issue multiple commands on a single connection (performs better than spawning single commands and parsing the results)

System Requirements

P4Python is supported on Windows, Linux, Solaris, and FreeBSD.

To build P4Python from source, your development machine must also have:

- Python 2.5.1 development files
- The 2007.3 Perforce C/C++ API for your target platform
- The same C++ compiler used to build the Perforce C++ API on your target platform.

(If you get “unresolved symbol” errors when building or running P4Python, you probably used the wrong compiler or the wrong Perforce API build.)

Installing P4Python

Download P4Python from the Perforce web site downloads page. After downloading, you can either run the installer or build the interface from source, as described in the release notes packaged with P4Python.

Programming with P4Python

P4Python provides an object-oriented interface to Perforce that is intended to be intuitive for Python programmers. Data is loaded and returned in Python arrays and dictionaries. Each P4 object represents a connection to the Perforce Server.

When instantiated, the P4 instance is set up with the default environment settings just as the command line client `p4`, that is, using environment variables, the registry on Windows and, if defined, the `P4CONFIG` file. The settings can be checked and changed before the connection to the server is established with the `connect()` method. After your script connects, it can send multiple commands to the Perforce Server with the same P4 instance. After the script is finished, it should disconnect from the Server by calling the `disconnect()` method.

The following example illustrates the basic structure of a P4Python script. The example establishes a connection, issues a command, and tests for errors resulting from the command.

```
from P4 import P4          # Import the module
p4 = P4()                  # Create the P4 instance
p4.port = "1666"
p4.user = "fred"
p4.client = "fred-ws"      # Set some environment variables

try:                        # Catch exceptions with try/except
    p4.connect()            # Connect to the Perforce Server
    info = p4.run("info")   # Run "p4 info" (returns a dict)
    s = info['serverVersion'] # Get server version
    p4.run("edit", "file.txt") # Run "p4 edit file.txt"
    p4.disconnect()         # Disconnect from the Server
except p4.P4Exception:
    for e in p4.errors:      # Display errors
        print e
```

This example creates a client workspace from a template and syncs it:

```
from P4 import P4, P4Exception
template = "my-client-template"
client_root = "C:\\work\\my-root"
p4 = P4()

try:
    p4.connect()
    # Convert client spec into a Python dictionary
    client = p4.fetch_client("-t", template)
    client._root = client_root
    p4.save_client(client)
    p4.run_sync()
except P4Exception:
    # If any errors occur, we'll jump in here. Just log them
    # and raise the exception up to the higher level
```

Submitting a Changelist

This example creates a changelist, modifies it and then submits it:

```
from P4 import P4
p4 = P4()
p4.connect()
change = p4.fetch_change()

# Files were opened elsewhere and we want to
# submit a subset that we already know about.
myfiles = ['//depot/some/path/file1.c', '//depot/some/path/file1.h']
change._description = "My changelist\nSubmitted from P4Python\n"
change._files = myfiles    # This attribute takes a Python list
```

Logging into Perforce using ticket-based authentication

On some servers, users might need to log in to Perforce before issuing commands. The following example illustrates login using Perforce tickets.

```
from P4 import P4
p4 = P4()
p4.user = "Sven"
p4.connect()
p4.run_login("MyPassword")
opened = p4.run_opened()

[...]
```

Changing your password

You can use P4Python to change your password, as shown in the following example:

```
from P4 import P4
p4 = P4()
p4.user = "Sven"
p4.password = "MyOldPassword"
p4.connect()
p4.run_password("MyOldPassword", MyNewPassword)
# p4.password is automatically updated with the encoded password
```

Timestamp conversion

Timestamp information in P4Python is normally represented as seconds since Epoch (with the exception of `P4.Revision`). To convert this data to a more useful format, use the following procedure:

```
import datetime
...
myDate = datetime.datetime.utcfromtimestamp( int(timestampValue) )
```

P4Python Classes

The P4 module consists of several public classes:

- P4
- P4Exception
- DepotFile
- Revision
- Integration
- Spec

The following tables provide more details about each public class.

P4

Perforce client class. Handles connection and interaction with the Perforce server. There is one instance of each connection.

The following table lists attributes of the class P4 in P4Python. The attributes are read- and writable unless indicated otherwise. The attributes can be strings, objects, or integers.

Attribute	Description
api_level	API compatibility level. (Lock server output to a specified server level.)
charset	Charset for Unicode servers.
client	P4CLIENT, the name of the client workspace to use.
cwd	Current working directory
errors	An array containing the error messages received during execution of the last command
exception_level	The exception level of the P4 instance. Values can be <ul style="list-style-type: none">• 0 : no exceptions are raised• 1 : only errors are raised as exceptions• 2: warnings are also raised as exceptions The default value is 2
host	P4HOST, the name of the host used
input	Input for the next command. Can be a string, a list or a dictionary.
maxlocktime	MaxLockTime used for all following commands

Attribute	Description
maxresults	MaxResults used for all following commands
maxscanrows	MaxScanRows used for all following commands
p4config_file	The location of the configuration file used (P4CONFIG). This attribute is read-only.
password	P4PASSWD, the password used.
port	P4PORT, the port used for the connection
prog	The name of the script
server_level	Returns the current Perforce server level
tagged	To disable tagged output for the following commands, set the value to 0 or False. By default, tagged output is enabled.
ticket_file	P4TICKETS, the ticket file location used
user	P4USER, the user under which the connection is run
version	The version of the script
warnings	An array containing the warning messages received during execution of the last command

The following table lists all public methods of the class P4. Many methods are wrappers around `P4.run()`, which sends a command to the Perforce Server. Such methods are provided for your convenience.

Method	Description
<code>connect()</code>	Connects to the Perforce Server.
<code>connected()</code>	Returns True if connected and the connection is alive, otherwise False.
<code>delete_spectype()</code>	Deletes the spec <i>spectype</i> . Equivalent to the command <code>P4.run("spectype", "-d")</code> .
<code>disconnect()</code>	Disconnects from the Perforce Server.
<code>identify()</code>	Returns a string identifying the P4Python module.
<code>fetch_spectype()</code>	Fetches the spec <i>spectype</i> . Equivalent to the command <code>P4.run("spectype", "-o")</code> .
<code>format_spectype()</code>	Converts the spec <i>spectype</i> into a string.
<code>parse_spectype()</code>	Parses a string representation of the spec <i>spectype</i> and returns a dictionary.
<code>run()</code>	Runs a command on the server. Needs to be connected, or an exception is raised.

Method	Description
<code>run_command()</code>	Runs the command <i>command</i> . Equivalent to <code>P4.run("command")</code> .
<code>run_filelog()</code>	This command returns a list of <code>DepotFile</code> objects. Specialization for the <code>run()</code> command.
<code>run_login()</code>	Logs in using the specified password.
<code>run_password()</code>	Convenience method: updates the password. Takes two arguments: <i>oldpassword</i> , <i>newpassword</i>
<code>run_submit()</code>	Convenience method for submitting changelists. When invoked with a change spec, it submits the spec. Equivalent to : <code>p4.input = myspec</code> <code>p4.run("submit", "-i")</code>
<code>save_spectype()</code>	Saves the spec <i>spectype</i> . Equivalent to the command <code>P4.run("spectype", "-i")</code> .

P4.P4Exception

Exception class. Instances of this class are raised when errors and/or (depending on the `exception_level` setting) warnings are returned by the server. The exception contains the errors in the form of a string. `P4Exception` is a subclass of the standard Python Exception class.

P4.DepotFile

Container class returned by `P4.run_filelog()`. Contains the name of the depot file and a list of `P4.Revision` objects.

Attribute	Description
<code>depotFile</code>	Name of the depot file
<code>revisions</code>	List of Revision objects

P4.Revision

Container class containing one revision of a `DepotFile` object.

Attribute	Description
<code>action</code>	Action that created the revision
<code>change</code>	Changelist number
<code>client</code>	Client workspace used to create this revision
<code>desc</code>	Short change list description
<code>depotFile</code>	The name of the file in the depot
<code>digest</code>	MD5 checksum of the revision
<code>fileSize</code>	File size of this revision
<code>integrations</code>	List of <code>P4.Integration</code> objects
<code>rev</code>	Revision
<code>time</code>	Timestamp (as <code>datetime.datetime</code> object)
<code>type</code>	File type
<code>user</code>	User that created this revision

P4.Integration

Container class containing one integration for a `Revision` object

Attribute	Description
<code>how</code>	Integration method (merge/branch/copy/ignored)
<code>file</code>	Integrated file
<code>srev</code>	End revision
<code>erev</code>	Start revision

P4.Spec

Class allowing access to the fields in a Perforce specification form.

Attribute	Description
<code>spec._fieldname</code>	Value associated with the field named <i>fieldname</i> .
<code>spec.permitted_fields</code>	Array containing the names of the fields that are valid for this spec object

Class P4

Description

Main interface to the Python client API.

This module provides an object-oriented interface to the Perforce SCM system. Data is returned in Python arrays and dictionaries (hashes) and input can also be supplied in these formats.

Each `P4` object represents a connection to the Perforce Server, and multiple commands may be executed (serially) over a single connection (which of itself can result in substantially improved performance if executing lots of perforce commands).

1. Instantiate your `P4` object
2. Specify your Perforce client environment
 - `client`
 - `host`
 - `password`
 - `port`
 - `user`
3. Set any options to control output or error handling:
 - `exception_level`
4. Connect to the Perforce Server
5. Run your Perforce commands
6. Disconnect from the Perforce Server

Instance Attributes

`p4.api_level` -> `int`

Contains the API compatibility level desired. This is useful when writing scripts using Perforce commands that do not yet support tagged output. In these cases, upgrading to a later server that supports tagged output for the commands in question can break your script. Using this method allows you to lock your script to the output format of an older

Perforce release and facilitate seamless upgrades. Must be called before calling `P4.connect()`.

```
from P4 import P4
p4 = P4()
p4.api_level = 57 # Lock to 2005.1 format
p4.connect()
...
p4.disconnect
```

For the API integer levels that correspond to each Perforce release, see:

<http://kb.perforce.com/?article=512>

p4.charset -> string

Contains the character set to use when connect to a Unicode enabled server. Do not use when working with non-Unicode-enabled servers. By default, the character set is the value of the `P4CHARSET` environment variable. If the character set is invalid, this method raises a `P4Exception`.

```
from P4 import P4
p4 = P4()
p4.client = "www"
p4.charset = "iso8859-1"
p4.connect()
p4.run_sync()
p4.disconnect()
```

p4.client -> string

Contains the name of your client workspace. By default, this is the value of the `P4CLIENT` taken from any `P4CONFIG` file present, or from the environment according to the normal Perforce conventions.

p4.cwd -> string

Contains the current working directory. Can be called prior to executing any Perforce command. Sometimes necessary if your script executes a `chdir()` as part of its processing.

```
from P4 import P4
p4 = P4()
p4.cwd = "/home/sven"
```

p4.errors -> list (read-only)

Returns an array containing the error messages received during execution of the last command.

```
from P4 import P4, P4Exception
p4 = P4()
try:
    p4.connect()
    p4.exception_level = 1      # ignore "File(s) up-to-date"
    files = p4.run_sync()
except P4Exception:
    for e in p4.errors:
        print e
finally:
    p4.disconnect()
```

p4.exception_level -> int

Configures the events which give rise to exceptions. The following three levels are supported:

- 0 disables all exception handling and makes the interface completely procedural; you are responsible for checking the `p4.errors` and `p4.warnings` arrays.
- 1 causes exceptions to be raised only when errors are encountered.
- 2 causes exceptions to be raised for both errors and warnings. This is the default.

For example

```
from P4 import P4
p4 = P4()
p4.exception_level = 1
p4.connect()      # P4Exception on failure
p4.run_sync()     # File(s) up-to-date is a warning - no exception raised
p4.disconnect()
```

p4.host -> string

Contains the name of the current host. It defaults to the value of `P4HOST` taken from any `P4CONFIG` file present, or from the environment as per the usual Perforce convention. Must be called before connecting to the Perforce server.

```
from P4 import P4
p4 = P4()
p4.host = "workstation123.perforce.com"
p4.connect()
...
p4.disconnect()
```

p4.input -> string | dict | list

Contains input for the next command.

Set this attribute prior to running a command that requires input from the user. When the command requests input, the specified data is supplied to the command. Typically, commands of the form `p4 cmd -i` are invoked using the `P4.save_spectype` methods, which retrieve the value from `p4.input` internally; there is no need to set `p4.input` when using the `P4.save_spectype` shortcuts.

You may pass a string, a hash, or (for commands that take multiple inputs from the user) an array of strings or hashes. If you pass an array, note that the first element of the array will be popped each time Perforce asks the user for input.

For example, the following code supplies a description for the default changelist and then submits it to the depot:

```
from P4 import P4
p4 = P4()
p4.connect()
change = p4.run_change( "-o" )[0]
change[ "Description" ] = "Autosubmitted changelist"
p4.input = change
p4.run_submit( "-i" )
p4.disconnect()
```

p4.maxlocktime -> int

Limit the amount of time (in milliseconds) spent during data scans to prevent the server from locking tables for too long. Commands that take longer than the limit will be aborted. The limit remains in force until you disable it by setting it to zero. See `p4 help maxlocktime` for information on the commands that support this limit.

p4.maxresults -> int

Limit the number of results Perforce permits for subsequent commands. Commands that produce more than this number of results will be aborted. The limit remains in force until you disable it by setting it to zero. See `p4 help maxresults` for information on the commands that support this limit.

p4.maxscanrows -> int

Limit the number of database records Perforce scans for subsequent commands. Commands that attempt to scan more than this number of records will be aborted. The limit remains in force until you disable it by setting it to zero. See `p4 help maxscanrows` for information on the commands that support this limit.

p4.p4config_file -> string (read-only)

Contains the name of the current P4CONFIG file, if any. This attribute cannot be set.

p4.password -> string

Contains your Perforce password or login ticket. If not used, takes the value of P4PASSWD from any P4CONFIG file in effect, or from the environment according to the normal Perforce conventions.

This password is also used if you later call `p4.run_login()` to log in using the 2003.2 and later ticket system. After running `p4.run_login()`, the attribute contains the ticket the allocated by the server.

```
from P4 import P4
p4 = P4()
p4.password = "mypass"
p4.connect()
p4.run_login()
```

p4.port -> string

Contains the host and port of the Perforce server to which you want to connect. It defaults to the value of P4PORT in any P4CONFIG file in effect, and then to the value of P4PORT taken from the environment.

```
from P4 import P4
p4 = P4()
p4.port = "localhost:1666"
p4.connect()
...
```

p4.prog -> string

Contains the name of the program, as reported to Perforce system administrators running `p4 monitor show -e`. The default is unnamed `p4-python script`

```
from P4 import P4
p4 = P4()
p4.prog = "sync-script"
puts( p4.prog )
p4.connect()
...
```

p4.server_level -> int (read-only)

Returns the current Perforce server level. Each iteration of the Perforce Server is given a level number. As part of the initial communication this value is passed between the client application and the Perforce Server. This value is used to determine the communication that the Perforce Server will understand. All subsequent requests can therefore be tailored to meet the requirements of this Server level.

This attribute is 0 before the first command is run, and is set automatically after the first communication with the server.

For the API integer levels that correspond to each Perforce release, see:

<http://kb.perforce.com/?article=571>

p4.tagged -> int

If 1 or True, `p4.tagged` enables tagged output. By default, tagged output is on.

```
from P4 import P4
p4 = P4()
p4.tagged = False
print p4.tagged
```

p4.ticket_file -> string

Contains the location of the `P4TICKETS` file

p4.user -> string

Contains the Perforce username. It defaults to the value of `P4USER` taken from any `P4CONFIG` file present, or from the environment as per the usual Perforce convention.

```
from P4 import P4
p4 = P4()
p4.user = "sven"
p4.connect()
...
p4.disconnect()
```

p4.version -> string

Contains the version of the program, as reported to Perforce system administrators in the server log.

```
from P4 import P4
p4 = P4()
p4.version = "123"
puts( p4.version )
p4.connect
...
```

p4.warnings -> list (read-only)

Contains the array of warnings that arose during execution of the last command

```
from P4 import P4, P4Exception
p4 = P4()
try:
    p4.connect()
    p4.exception_level = 2 # File(s) up-to-date is a warning
    files = p4.run_sync()
except P4Exception, ex:
    for w in p4.warnings:
        print w
finally:
    p4.disconnect()
```

Class Methods**P4.P4()**

Construct a new P4 object. For example:

```
from P4 import P4
P4.P4()
```

P4.identify()

Return the version of P4 that you are using.

```
python -c "from P4 import P4; print P4.identify()"
```

Instance Methods**p4.connect()**

Initializes the Perforce client and connects to the server.

If the connection is successfully established, returns `None`. If the connection fails and `exception_level` is 0, returns `False`, otherwise raises a `P4Exception`. If already connected, prints a message.

```
from P4 import P4
p4 = P4()
p4.connect()
```

p4.connected() -> boolean

Returns true if connected to the Perforce Server and the connection is alive, otherwise false.

```
from P4 import P4
p4 = P4()
print p4.connected()
p4.connect()
print p4.connected()
```

p4.delete_<spectype>([options], name) -> list

The `delete_spectype` methods are shortcut methods that allow you to delete the definitions of clients, labels, branches, etc. These methods are equivalent to:

```
p4.run( <spectype>, '-d', [options], <spec name> )
```

The following code uses `delete_client` to delete client workspaces that have not been accessed in more than 365 days:

```
from P4 import P4, P4Exception
from datetime import datetime, timedelta
now = datetime.now()
p4 = P4()
try:
    p4.connect()
    for client in p4.run_clients():
        atime = datetime.utcfromtimestamp( int( client[ "Access" ] ) )
        # If the client has not been accessed for a year, delete it
        if ( atime + timedelta(365) ) < now :
            p4.delete_client( '-f', client[ "client" ] )
except P4Exception:
    for e in p4.errors:
        print e
finally:
    p4.disconnect()
```

p4.disconnect()

Disconnect from the Perforce Server. Call this method before exiting your script.

```
from P4 import P4
p4 = P4()
p4.connect()
...
p4.disconnect()
```

p4.fetch_<spectype>() -> P4.Spec

The `fetch_spectype` methods are shortcuts for running `p4.run("spectype", "-o").pop(0)`. For example:

```
label      = p4.fetch_label(labelname)
change     = p4.fetch_change(changeno)
clientspec = p4.fetch_client(clientname)
```

are equivalent to

```
label      = p4.run("label", "-o", labelname)[0]
change     = p4.run("change", "-o", changeno)[0]
clientspec = p4.run("client", "-o", clientname)[0]
```

p4.format_spec(<spectype>, dict) -> string

Converts the fields in the dict containing the elements of a Perforce form (spec) into the string representation familiar to users. The first argument is the type of spec to format: for example, client, branch, label, and so on. The second argument is the hash to parse.

There are shortcuts available for this method. You can use `p4.format_spectype(dict)` instead of `p4.format_spec(spectype, dict)`, where `spectype` is the name of a Perforce spec, such as client, label, etc.

p4.format_<spectype>(dict) -> string

The `format_spectype` methods are shortcut methods that allow you to quickly fetch the definitions of clients, labels, branches, etc. They're equivalent to:

```
p4.format_spec( spectype, dict )
```

p4.parse_spec(<spectype>, string) -> P4.Spec

Parses a Perforce form (spec) in text form into a Python dict using the spec definition obtained from the server. The first argument is the type of spec to parse: client, branch, label, and so on. The second argument is the string buffer to parse.

There are shortcuts available for this method. You can use:

```
p4.parse_spectype( buf )
```

instead of

```
p4.parse_spec( spectype, buf )
```

where `spectype` is one of client, branch, label, and so on.

p4.parse_<spectype>(string) -> P4.Spec

This is equivalent to `parse_spec(spectype, string)`.

For example, `parse_job(myJob)` converts the String representation of a job spec into a Spec object.

To parse a spec, P4 needs to have the spec available. When not connected to the Perforce Server, P4 assumes the default format for the spec, which is hardcoded. This assumption can fail for jobs if the Server's jobspec has been modified. In this case, your script can load a job from the Server first with the command `fetch_job('somename')`, and P4 will cache and use the spec format in subsequent `parse_job()` calls.

p4.run(cmd, [arg, ...])

Base interface to all the run methods in this API. Runs the specified Perforce command with the arguments supplied. Arguments may be in any form as long as they can be converted to strings by `str()`.

The `p4.run()` method returns a list of results whether the command succeeds or fails; the list may, however, be empty. Whether the elements of the array are strings or dictionaries depends on

- (a) server support for tagged output for the command, and
- (b) whether tagged output was disabled by calling `p4.tagged = False`.

In the event of errors or warnings, and depending on the exception level in force at the time, `run()` raises a `P4Exception`. If the current exception level is below the threshold for the error/warning, `run()` returns the output as normal and the caller must explicitly review `p4.errors` and **p4.warnings** to check for errors or warnings.

```
from P4 import P4
p4 = P4()
p4.connect()
spec = p4.run( "client", "-o" )[0]
p4.disconnect()
```

Shortcuts are available for `p4.run`. For example, `p4.run_command(args)` is equivalent to `p4.run("command", args)`

There are also some shortcuts for common commands such as editing Perforce forms and submitting. For example, this:

```
from P4 import P4
p4 = P4()
p4.connect()
clientspec = p4.run_client( "-o" ).pop(0)
clientspec[ "Description" ] = "Build client"
p4.input( clientspec )
p4.run_client( "-i" )
p4.disconnect()
```

...may be shortened to

```
from P4 import P4
p4 = P4()
p4.connect()
clientspec = p4.fetch_client()
clientspec[ "Description" ] = "Build client"
p4.save_client( clientspec )
p4.disconnect()
```

The following are equivalent:

Shortcut	Equivalent to
<code>p4.delete_spectype</code>	<code>p4.run("spectype", "-d ")</code>
<code>p4.fetch_spectype</code>	<code>p4.run("spectype", "-o ").shift</code>
<code>p4.save_spectype(spec)</code>	<code>p4.input = spec; p4.run("spectype", "-i")</code>

As the commands associated with `fetch_spectype` typically return only one item, these methods do not return an array, but instead return the first result element.

For convenience in submitting changelists, changes returned by `fetch_change()` can be passed to `run_submit()`. For example:

```
from P4 import P4
p4 = P4()
p4.connect()
spec = p4.fetch_change()
spec[ "Description" ] = "Automated change"
p4.run_submit( spec )
p4.disconnect
```

p4.run_<cmd>()

Shorthand for `p4.run("cmd", arguments...)`

p4.run_filelog(<fileSpec >) -> list

Runs a `p4 filelog` on the `fileSpec` provided and returns an array of `P4.DpotFile` results (when executed in tagged mode), or an array of strings when executed in nontagged mode. By default, the raw output of `p4 filelog` is tagged; this method restructures the output into a more user-friendly (and object-oriented) form.

For example:

```
from P4 import P4, P4Exception
p4 = P4()
try:
    p4.connect()
    for r in p4.run_filelog( "index.html" )[0].revisions:
        for i in r.integrations:
            # Do something
except P4Exception:
    for e in p4.errors:
        print e
finally:
    p4.disconnect()
```

p4.run_login(arg...) -> list

Runs `p4_login` using a password (or other arguments) set by the user.

p4.run_password(oldpass, newpass) -> list

A thin wrapper to make it easy to change your password. This method is (literally) equivalent to the following:

```
p4.input( [ oldpass, newpass, newpass ] )
p4.run( "password" )
```

For example

```
from P4 import P4, P4Exception
p4 = P4()
p4.password = "myoldpass"
try:
    p4.connect()
    p4.run_password( "myoldpass", "mynewpass" )
except P4Exception:
    for e in p4.errors:
        print e
finally:
    p4.disconnect()
```

p4.run_submit([hash], [arg...]) -> list

Submit a changelist to the server. To submit a changelist, set the fields of the changelist as required and supply any flags:

```
change = p4.fetch_change()
change._description = "Some description"
p4.run_submit( "-r", change )
```

You can also submit a changelist by supplying the arguments as you would on the command line:

```
p4.run_submit( "-d", "Some description", "somedir/..." )
```

p4.save_<spectype>()

The `save_<spectype>` methods are shortcut methods that allow you to quickly update the definitions of clients, labels, branches, etc. They are equivalent to:

```
p4.input = dictOrString
p4.run( spectype, "-i" )
```

For example:

```
from P4 import P4, P4Exception
p4 = P4()
try:
    p4.connect()
    client = p4.fetch_client()
    client[ "Owner" ] = p4.user
    p4.save_client( client )
except P4Exception:
    for e in p4.errors:
        print e
finally:
    p4.disconnect()
```

Class P4.P4Exception

Description

Instances of this class are raised when P4 encounters an error or a warning from the server. The exception contains the errors in the form of a string. `P4Exception` is a shallow subclass of the standard Python `Exception` class.

Class Attributes

None.

Class Methods

None.

Class P4.DpotFile

Description

Utility class providing easy access to the attributes of a file in a Perforce depot. Each `P4.DpotFile` object contains summary information about the file and a list of revisions (`P4.Revision` objects) of that file. Currently, only the `P4.run_filelog` method returns a list of `P4.DpotFile` objects.

Instance Attributes

df.depotFile -> string

Returns the name of the depot file to which this object refers.

df.revisions -> list

Returns a list of `P4.Revision` objects, one for each revision of the depot file.

Class Methods

None.

Instance Methods

None.

Class P4.Integration

Description

Utility class providing easy access to the details of an integration record. Created by `P4.run_filelog()`.

Instance Attributes

integ.how -> string

Returns the type of the integration record - how that record was created.

integ.file -> string

Returns the path to the file being integrated to/from.

integ.erev -> int

Returns the end revision number used for this integration.

integ.srev -> int

Returns the start revision number used for this integration.

Class Methods

None.

Instance Methods

None.

Class P4.Revision

Description

Utility class providing easy access to the revisions of `P4.DepotFile` objects. Created by `P4.run_filelog()`.

Instance Attributes

rev.action -> string

Returns the name of the action which gave rise to this revision of the file.

rev.change -> int

Returns the change number that gave rise to this revision of the file.

rev.client -> string

Returns the name of the client from which this revision was submitted.

rev.depotFile -> string

Returns the name of the depot file to which this object refers.

rev.desc -> string

Returns the description of the change which created this revision. Note that only the first 31 characters are returned unless you use `p4 filelog -L` for the first 250 characters, or `p4 filelog -l` for the full text.

rev.digest -> string

Returns the MD5 checksum of this revision.

rev.fileSize -> string

Returns this revision's size in bytes.

rev.integrations -> list

Returns the list of `P4.Integration` objects for this revision.

rev.rev -> int

Returns the number of this revision of the file.

rev.time -> datetime

Returns the date/time that this revision was created.

rev.type -> string

Returns this revision's Perforce filetype.

rev.user -> string

Returns the name of the user who created this revision.

Class Methods

None.

Instance Methods

None.

Class P4.Spec

Description

Utility class providing easy access to the attributes of the fields in a Perforce form.

Only valid field names may be set in a `P4.Spec` object. Only the field name is validated, not the content. Attributes provide easy access to the fields.

Instance Attributes

`spec._<fieldname>` -> string

Contains the value associated with the field named *<fieldname>*.

`spec.permitted_fields` -> dict

Contains an array containing the names of fields that are valid in this spec object. This does not imply that values for all of these fields are actually set in this object, merely that you may choose to set values for any of these fields if you want to.

Class Methods

`P4.Spec.new(dict)` -> `P4.Spec`

Constructs a new `P4.Spec` object given an array of valid fieldnames.

Instance Methods

None.
